This work was supported by the «Iuventus Plus» grant from the Polish Ministry of Science and Higher Education (IP2011018771).

The emergence and spread of drug-resistant tuberculosis (DR-TB), including multidrug-resistant (MDR)-TB (defined as resistance to at least two most potent anti-TB drugs: isoniazid [INH] and rifampicin [RMP]) and extensively drug-resistant (XDR)-TB (defined as MDR-TB with additional resistance to any fluoroquinolone [FQ] and one of the three injectable drugs: amikacin [AMK], kanamycin [KAN], or capromycin [CAP]) have further aggravated the existing health threat of TB worldwide. Effective DR-TB prevention and control require rapid and reliable methods to identify resistant drug-resistant Mycobacterium tuberculosis strains. Mutations in several genetic loci have been implicated in the development of resistance of tubercle bacilli to second line anti-TB drugs (SLDs).

The purpose of this study was to investigate the prevalence of resistance to SLDs and its association with resistance-related mutations in MDR M. tuberculosis clinical isolates.

Of the 46 MDR M. tuberculosis isolates, 14 (30.4%) showed resistance to at least one of the four SLDs tested. Nine (19.5%) isolates were resistant to both OFX (7; 15.2%) or AMK (2; 4.3%), and thus met the definition of pre-XDR-TB, whereas 3 (6.5%) isolates were resistant to OFX and AMK (2; 4.3%) or CAP (1; 2.2%) simultaneously and were categorized as XDR-TB isolates. Four (8.7%) isolates, including two pre-XDR isolates, were resistant to ETH.

None of the AMK-resistant isolates carried a mutation in the rsr gene. All isolates were wild-type of the tlyA locus. Mutations in the gyrA gene occurred in 34 (73.9%) isolates, with the most common amino acid change being Ser95Thr, found in 5 OFX-resistant and 25 OFX-susceptible isolates. The Asp94Asn and Gly93Glu substitutions were present exclusively in OFX-resistant strains, yet represented only 40% of all OFX-resistant isolates. The only mutation in the gyrB gene was substitution Ser477Phe, detected in one OFX-resistant isolate. Mutations in the ethA gene were found in one ETH-resistant and 11 ETH-susceptible isolates.

Apart from two gyrA mutations (at codons 90 and 94), none of the amino acid changes detected in all six loci tested were associated with resistance to SLDs. This casts doubt over the usefulness of sequence analyses of these genes for the prediction of SLD resistance pattern. Other genetic loci need to be considered for detection of mutations conferring resistance to SLDs.
